Cover

The cover flood picture is the Unitarian Church in Bowling Green, Kentucky. This is the 2nd time it has flooded since 2010. The sinkhole it sits in drains a surface area of about 40 acres. In 2010 it flooded to the bottom of the arch. It reached the peak flood level 48 hours after the rain stopped. That was not surface flooding. Lost River Cave passes under the sinkhole and drains an area of about 50 square miles. This sinkhole and church floods from below.

Preface to the 2022 Survey

This is a monumental year for the survey. After 15 years of hard work, we finally passed 2000 stormwater utilities (SWUs) which is quite a jump from 1851 in the 2021 survey. I stumbled onto a Library of Congress web site that showed several online municipal code publishers. I scoured some of these and was able to find SWUs in many of the smaller towns whose websites were minimal and often not up to date. Some of these had populations below 1000. From these websites, I could have easily gotten to 2100, but you must stop and publish sometime. Based on the rate of find, I am confident there are at least 2500 SWUs in the U.S., and quite possibly 3000.

We now know that at least 9 states have more than 100 SWUs. Anchorage, Alaska and New Orleans have done feasibility studies, and Louisiana has passed enabling legislation. East Baton Rouge has proposed a stormwater utility. Officials in Oahu and Honolulu have also proposed utilities. At one time, New Hampshire was considering a statewide SWU. It seems to me that with western reservoirs at historically low levels while historic floods occur that some of the western states should consider a statewide SWU to deal with some of these issues.

With more than 2000 SWUs in the database, it is very difficult to keep fees and some other information up to date. As I always, I appreciate corrections from readers. Please send your information to warren.campbell@wku.edu.

Methods

The main goal of this survey is to identify as many U.S. Stormwater Utilities (SWUs) as possible. Because many stormwater professionals do not have the time to respond to questionnaires, our primary method of identification was Internet searches. We searched on key terms such as “stormwater utility”, “stormwater fee”, and “drainage fee”. We scoured on-line municipal codes such as Municode, AmLegal, Sterling, LexisNexis, General Code, and others. We searched through many city web sites trying to find utilities. We have also had many people contact me to update fees and identify new utilities. However, the data primarily comes from Internet sources and is prone to errors. Some community websites are not very clear on whether the fee given is monthly, bi-monthly, quarterly, or annually. In cases like that we made the best guess we could. We hope the readers of this document will continue to help us correct mistakes. However, it is difficult to keep up with fee changes in more than 2000 utilities, so if you discover errors in our data please contact me at warren.campbell@wku.edu.

ACKNOWLEDGEMENTS

I am indebted to the Wisconsin chapter of the American Public Works Association for their excellent survey of Wisconsin SWUs (Wisconsin APWA [2019]).

I want to thank Mike Gregory of Computational Hydraulics International for his updates on Canadian stormwater utilities. Also, the University of North Carolina Environmental Finance Center has identified several SWUs that I have included in this survey.

I also want to thank Andy Reese of AMEC (now Wood) for showing me several SWUs as well.

Black and Veatch (2021) publishes an excellent stormwater utility survey with more detailed information about the SWUs in their survey. In 2021 73 SWU communities responded to their survey. It is a very worthwhile survey and should be read by anyone interested in stormwater utilities.

The author is grateful to Professor Randel Dymond and his graduate students Kandace Kea and Amanda Dritschel at Virginia Tech for work they did on past surveys and the database.

Since 2007, many of the SWUs in this survey were identified by our undergraduate students who are listed below. I am very proud of the fact that 64 of my students have passed the Certified Floodplain Manager (CFM) exam. When I came to Kentucky in 2004, I was the 7th CFM in the state. There are 11 states with fewer than 64 CFMs so we are making a contribution to floodplain management.

The author is grateful to all of these students who have participated in the survey over the past years. They have worked diligently at a somewhat tedious job, but one that should have taught them something about stormwater financing, municipal codes, and websites.

We are also indebted to AMEC for sharing their list of stormwater utilities with us. In 2008, Scott Embry had the foresight to ask them for it and they obliged. We continue to have a good relationship with AMEC and with Andy Reese.

I also wish to thank the Environmental Finance Center of the University of North Carolina which provided data on several North Carolina and Georgia stormwater utilities (Environmental Finance Center, 2013).

Several companies publish municipal and county codes which serve as a source for much of our data. We are particularly indebted to the Municipal Code Corporation, American Legal Publishing Corporation, General Code, Lexis Nexis, and Sterling Codifiers, Inc.

Introduction

We have been able to identify 2057 U.S. stormwater utilities that have formed nationwide, and Mike Gregory found 62 in Canada. There are now 2 states with more than 200 stormwater utilities (SWUs) and nine with 100 or more SWUs. Minnesota leads with 229. Forty-one states and DC have at least one SWU. North Carolina is the latest member of the 100 SWU club. Figure 1 shows U.S. stormwater utilities by location.

As Figure 1 shows, one of the very disappointing aspects of the SWU map is that Louisiana and Mississippi have missed a golden opportunity to encourage stormwater utilities. Seventeen years after Hurricane Katrina, and 10 years after Sandy neither of the hardest hit states have formed a SWU as far as we can tell. However, New Orleans is considering a stormwater utility to maintain their extensive flood protection systems, and East Baton Rouge officials have proposed a SWU. Louisiana has passed enabling legislation. Oahu, Hawaii and Anchorage, Alaska are also considering stormwater utilities, and in 11 years at least 59 have formed in Pennsylvania.

One community official said, “We are too small to have a stormwater utility.” The smallest community with a stormwater utility that we have found is Indian Creek Village, Florida with a 2020 census population of 84 (no, this is not a misprint). The largest community is Los Angeles County with a population of over 10,000,000. The average SWU community population is 208,001 and the median is 16,569. These numbers are almost certainly too large because it is difficult to find stormwater utilities in small communities. The bottom line is that no community is too small nor too large to have a stormwater utility.

At some point, this survey will become unnecessary as every community will have some appropriate stormwater funding mechanism. When will this occur? We have identified 2057 SWUs in the U.S. and 62 in Canada, and in June 2019 there were 22,389 communities participating in the National Flood Insurance Program (NFIP) (FEMA’s Community Status Book: <https://www.fema.gov/cis/nation.pdf>). This survey will be necessary for some years to come.

The Data

Part of our raw data is contained in the Table in Appendix A. As this is written, our survey contains data on 2057 stormwater utilities (SWUs) located in 41 states and the District of Columbia (Figure 1). Based on our current find rate, my best guess would be that there are at least 2500 SWUs in the U.S., and quite possibly, 3000. More are being formed all the time and we are aware of several that will form within the next few months.

Figure 2 shows the number of stormwater utilities by state. It also emphasizes that SWU formation is not governed by politics. If SWUs were electoral votes, Trump would have won 1209 to 957. It is interesting that conservative states have more stormwater utilities than more liberal states.

At least 9 states have more than 100 SWUs. Democratic leaning Washington, Wisconsin, and Minnesota have more than 100 SWUs while conservative leaning Texas, Ohio, Iowa, Indiana, North Carolina, and Florida also have more than 100. There are 4 states that went for Biden in the 2020 election and 4 that went for Trump that had no SWUs I could find.

Nationwide, the average monthly single-family residential fee was \$6.01, the standard deviation was \$4.69, and the median fee was \$5.00. Most fees go up over time reflecting an increase in the Consumer Price Index (CPI). Some communities tie the monthly fee to the CPI. However, a few communities have reduced their fees. The quartile fees are: 25% - \$3.00 and 75% - \$7.34 for an interquartile range of \$4.34. The median population of a U.S. SWU community was 16,569. This is probably a biased statistic since it is often harder to find SWUs in smaller communities.

Fees ranged from zero up to \$45 per month. Figure 3 shows the spatial distribution of monthly fees. As has been observed in previous surveys, no state has all high fees. Even states with the higher fees also have utilities with much lower fees. The range of fee amounts probably reflects stormwater needs and local political realities.

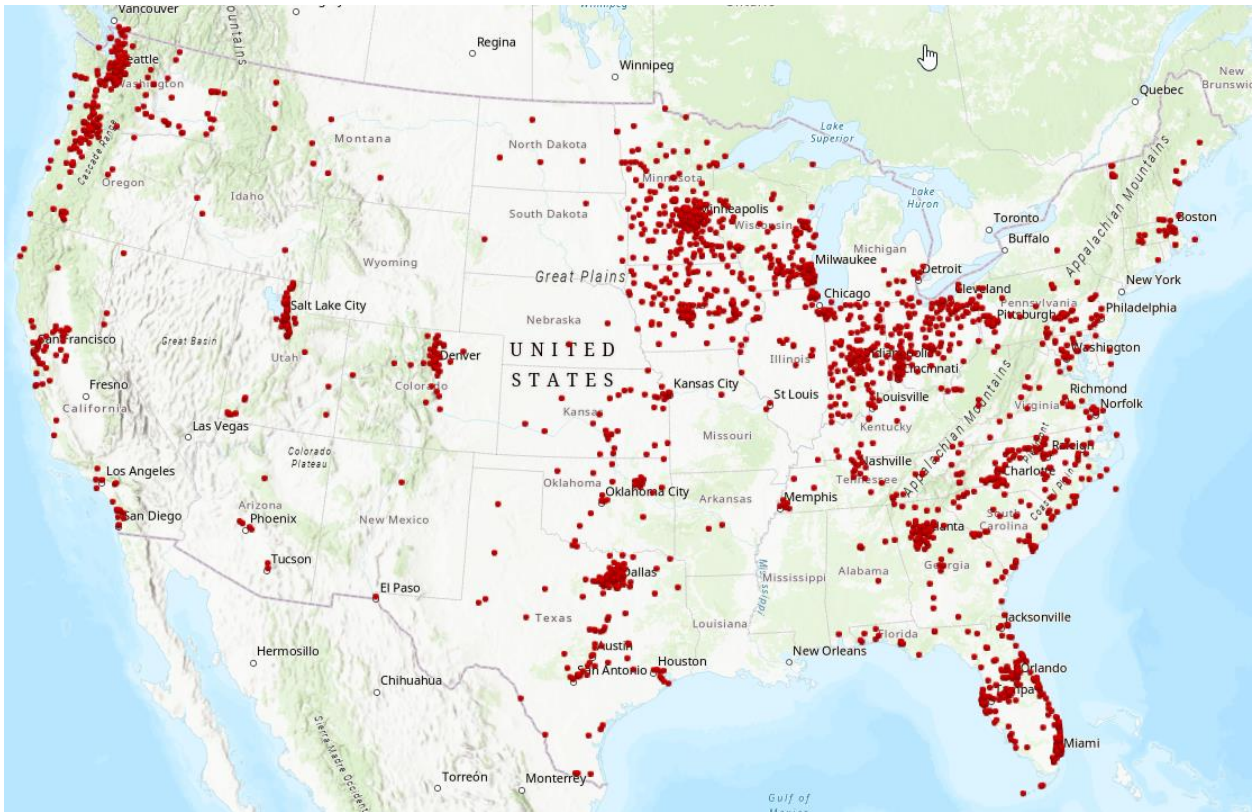

Figure 1. U.S. stormwater utilities (SWUs).

The most widely used method of funding is the ERU system. An Equivalent Residential Unit is usually the average impervious area on a single-family residential parcel, although some communities define it as the average of all residential parcels. Fees for non-residential properties are proportional to the ratio of the parcel impervious area to the ERU. For the ERUs identified in our survey, the average was 3120 sq ft impervious area, the median was 3000 sq ft, and the standard deviation of 1424 sq ft. We were able to find ERUs for 1007 utilities which is just over half of the SWUs for which I could identify the fee type. It is important to have a good estimate of the ERU because an inaccurate ERU means that someone is paying a disproportionate amount which could increase legal exposure (Campbell [2010]). The second and third most popular fee systems were the flat fee (249 SWUs) and the tier fee (245 SWUs) systems. Next in popularity was the Residential Equivalent Factor (REF) system with 150 identified. We were able to identify 116 Dual Fee systems.

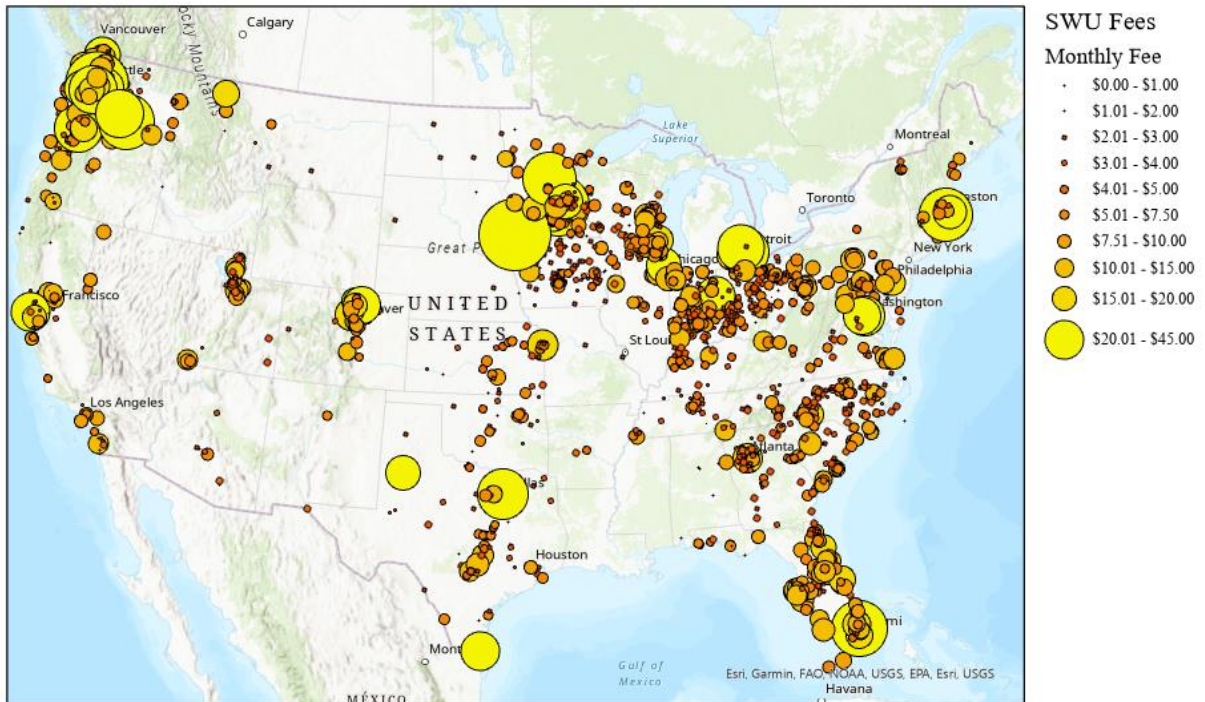

Figure 2. Number of stormwater utilities by state.

A few communities use ERU systems with a cap. For example, I am aware of one community with an ERU system that caps at \$60. In that community there is at least one property owner that should be paying 10 times that \$60 dollar cap per month. In a community like this the residential customers will be paying much more than their fair share of the cost of the stormwater program. This increases the legal exposure for the community. Presumably, community officials have balanced legal exposure with the need to pass the utility ordinance and decided the additional legal exposure was worth the risk.

Stormwater Utility Fees 2022

Figure 3. Spatial distribution of monthly stormwater fees.

Canadian Stormwater Utilities

Mike Gregory found 62 Canadian communities with stormwater utilities. From Figure 4, SWUs in Canada seem to mostly cluster in tight groupings near metropolitan areas.

The average fee was \$11.62 Canadian and the median was \$10.00. The median population of a SWU community was 38,750. Comparing U.S. SWUs and Canadian SWUs, we see several differences. The ERU fee was most popular in the U.S. but was much less popular in Canada where only 3 of 62 used it. The most popular fee there was the flat fee with 21 of 62 using it., followed by the dual fee with 15 using it. The median population of a SWU community in Canada was 2.3 times larger than the median population in the U.S.

Figure 5 provides the distribution of Canadian monthly fees in Canadian dollars. All information to create these maps was provided by Mike Gregory, Engineering Director for Computational Hydraulics International.

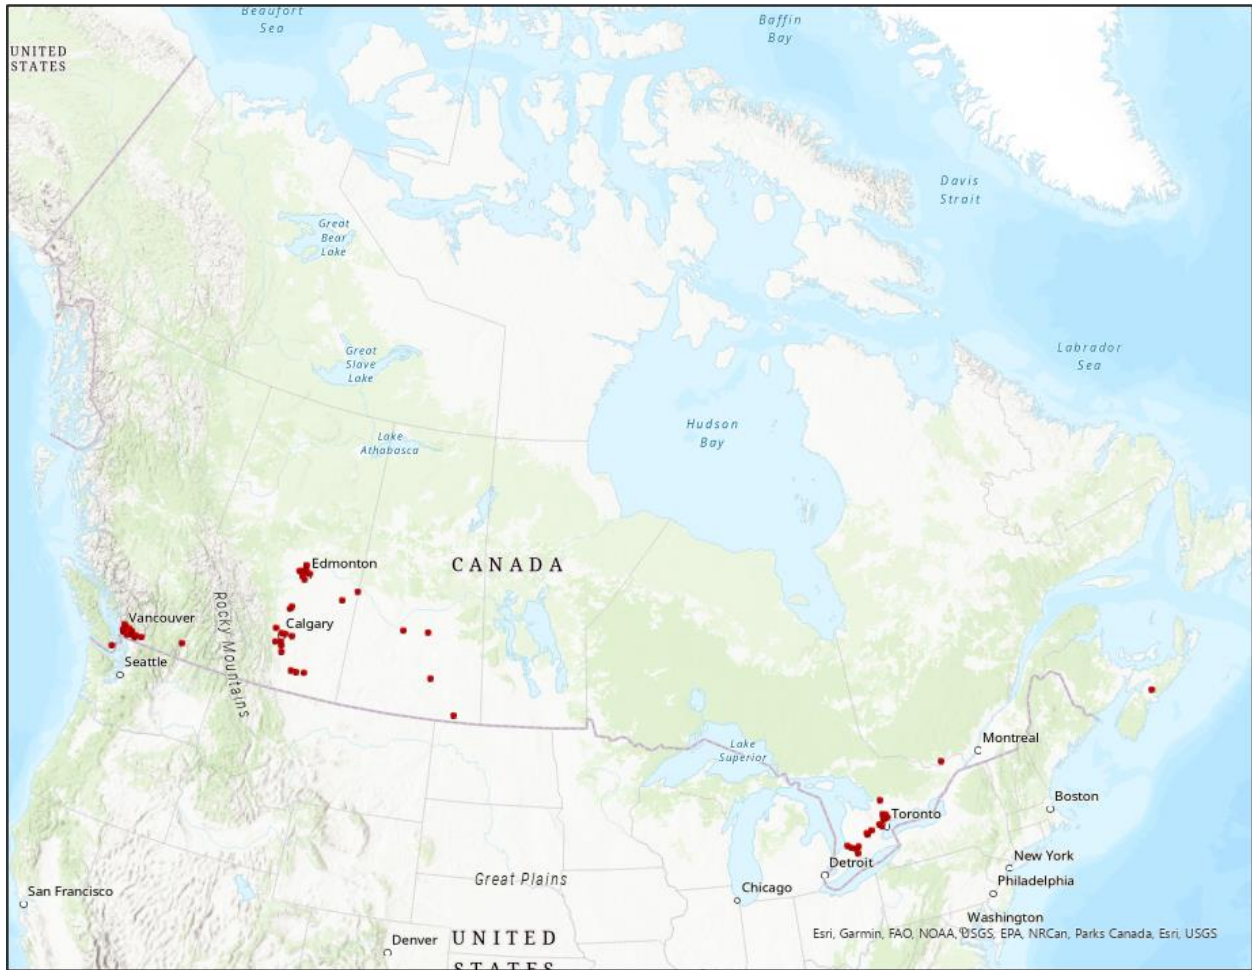

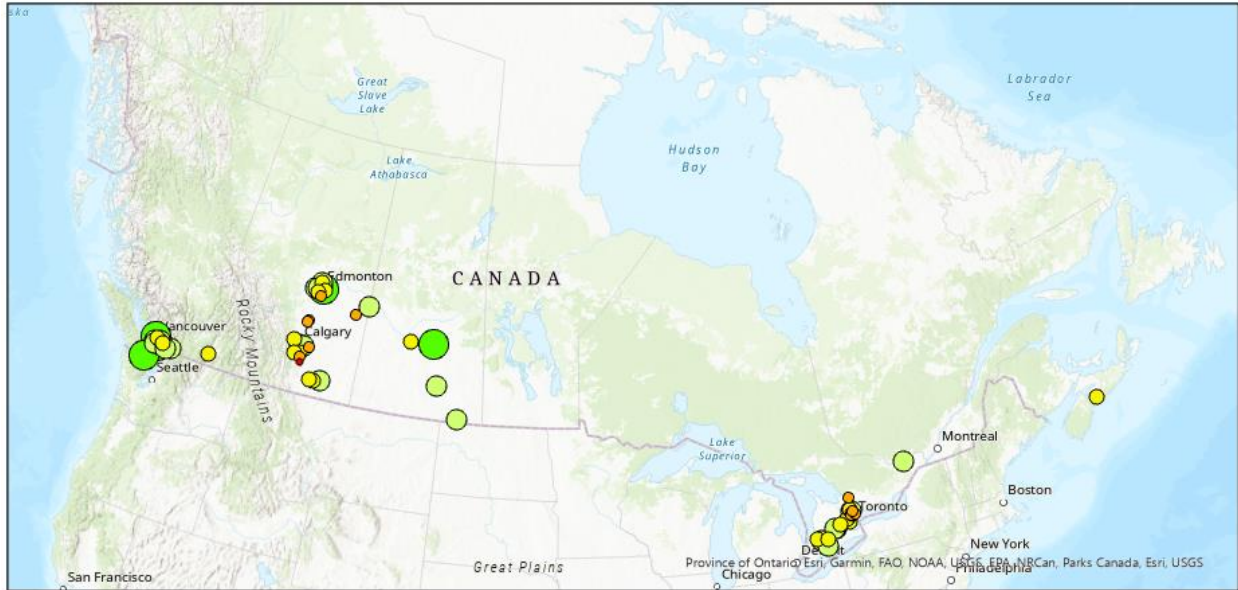

Figure 4. Canadian communities with stormwater utilities.

2022 Monthly Fees in Canadian Dollars

Monthly Fees

- \$0.00 - \$2.00
- \$2.01 - \$5.00
- \$5.01 - \$10.00
- \$10.01 - \$20.00
- \$20.01 - \$50.00

Bubble sizes are proportional to the fee amount.

Information provided by Mike Gregory

Figure 5. Canadian monthly fees

Fee Systems

Fee systems can be made fair, but they are not inherently so. Fair systems charge fees in proportion to their stormwater production. We will expand on the methods of creating both fair and unfair fee systems.

Beginning with the most popular fee system, the Equivalent Residential Unit or ERU, the following example is meant to encourage the use of an accurate ERU. An ERU is sometimes given different names like Equivalent Service Unit or others. However, it comes to the same thing. It is the average or median impervious area of a single-family residential property. Nonresidential properties are charged in accordance with the number of ERUs on the property. An ERU can be obtained in several ways. One is to take a random sample of residential properties and get the average impervious area of these. The result is the ERU to be used. Another approach using multispectral aerial photography and/or lidar to estimate the total impervious area (IA) of residential properties. This IA is divided by the number of residential properties to obtain an ERU. Consider the following example.

Number of residential parcels = 50,000

Nonresidential impervious area = 15×10^7 sq ft

Accurate ERU = 3000 sq ft

Annual revenue needed for selected level of service = \$12M

Every residential customer pays the 1 ERU fee.

Using the accurate ERU the city has 100,000 ERUs total which implies that the monthly base fee should be \$10 to raise the required amount of money needed. In this case 50 percent of the cost is borne by residential customers and 50 percent by nonresidential customers.

For political reasons suppose the city decides to use 4000 sq ft instead of 3000 sq ft as the ERU. This gives a total 87,500 ERUs total. Then the base fee would have to be \$11.43 and residential customers would pay 4/7 or about 57 percent of the cost and nonresidential customers 3/7 or 43 percent of the total cost.

Alternatively, if we used a 2000 sq ft as the ERU, the total ERUs would be 125,000, the base fee \$8, residential customers would pay 40 percent, and nonresidential customers 60 percent. These considerations show the importance of obtaining and using an accurate ERU. For this example, Figure 6 shows the variation in the fractions paid by residential and nonresidential customers when the ERU used is varied. If the ERU is 3000 but 1000 is used, residential customers pay 25 percent of the cost for the stormwater program and nonresidential customers pay 75%. When 5000 sq ft is used residential customers pay 62.5 percent and nonresidential pay 37.5 percent. Using an accurate ERU is important. The graph is for this one example but the general equation is given below. The fraction paid by nonresidential customers is just one minus the fraction paid by residential customers. The two equations are plotted in Figure 6 for this example. This may appear to be a contrived situation, but I know of one community that uses more than 10,000 sq ft IA with no real justification.

$$Frac_{res} = \frac{ERUs_{res}}{ERUs_{res} + \frac{IA_{nonres}}{ERU_{used}}} \quad (1)$$

$Frac_{res}$ = fraction of stormwater program paid by residential customers

$ERUs_{res}$ = total number of residential ERUs in the city

IA_{nonres} = total nonresidential impervious area in town

ERU_{used} = the actual ERU used as opposed to the true ERU

$$Frac_{nonres} = 1 - Frac_{res} \quad (2)$$

An ERU can change, or in some cases can be made more correct. I see that San Marcos, Texas proposed raising their ERU from 2250 to 2575 and Longview, Washington from 2500 to 3000 sq ft.

Figure 6. Percent paid by residential and nonresidential customers.

The second most popular system is the tier system. Tier systems can be made relatively fair, but usually are not. Figure 7 shows an example of an unfair tier system. The chart shows the ERU fee as a straight line and the staircase is the actual tier system. It is clear that very large properties are not paying near their fair share of cost while small businesses are severely overcharged. This system can be made fair by changing the tier system. We can build the fair system by beginning with a minimum amount of impervious area that will have a stormwater charge. For this example, we chose 500 sq ft impervious area as the minimum impervious area to charge. The goal is to minimize the deviation of the relative error at each end of a tier. It is minimized if the relative errors are equal but opposite in sign at each end of a tier. A simple analysis results in the following equations.

$$IA_i = \frac{1 + E}{1 - E} IA_{i-1} \quad (3)$$

$$C_i = \frac{1 + E}{1 - E} C_{i-1} \quad (4)$$

$$C_{T_i} = (1 + E) C_{i-1} \quad (5)$$

C_i = ERU fee at the end of the i th tier

C_{i-1} = ERU fee at the beginning of the i th tier

E = acceptable maximum relative error

C_{T_i} = tier fee for the i th tier

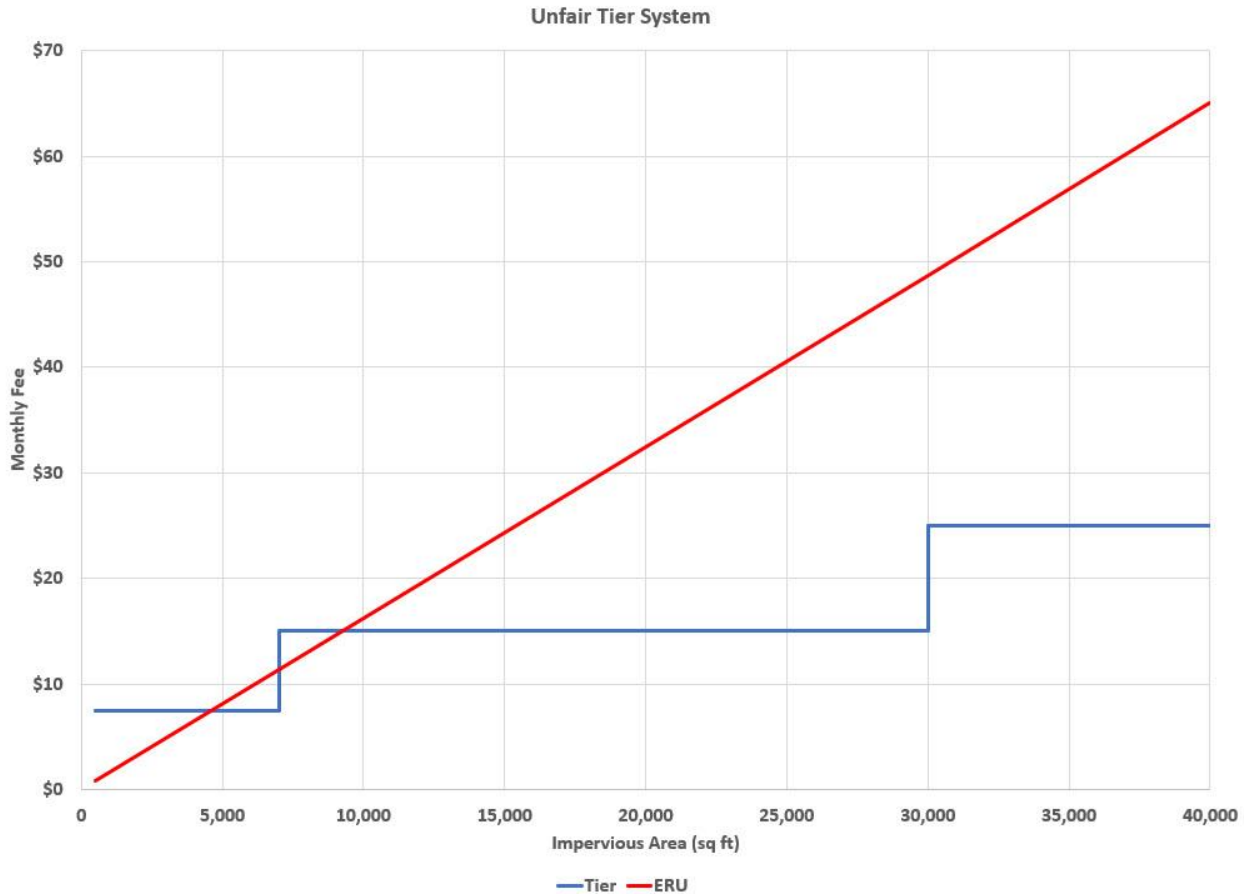

Figure 7. Example of an unfair tier system.

To construct a fair tier system, beginning with 500 sq ft of impervious area, use Equation 5 to determine the 1st tier fee, then use Equation 3 to determine the impervious area at the end of the first tier. The process is repeated to build subsequent tiers. Figure 8 shows the resulting tier system. The relative deviation from the ERU fee at the end of each tier is 50 percent since 50% was the acceptable relative error.

Another practice apparently done for political reasons is the capping of ERU or tier systems. An extreme case is capping the fee at 10 ERUs. That is, any parcel with more than 10 ERUs of impervious area would pay only a 10 ERU fee. Take a simple example of a small to medium Walmart which can have 750,000 sq ft of impervious area including building, sidewalks, and parking lot. If the base monthly fee is \$5 and the ERU is 3000 sq ft, then the Walmart should be paying \$1250 per month. With a 10 ERU cap, they would pay only \$50 per month. This is problematic and would mean that residential customers would be paying much more than their fair share. This could lead to legal exposure for the SWU.

Figure 8. Fair tier system example.

Another common fee system is the flat fee. There is no way to make a flat fee fair. The same can be said of dual fee systems. Flat fee and dual fee systems are just tier systems with 1 or 2 tiers and ERU systems are tier systems with infinite numbers of tiers. Flat and dual fees can, and often are used to raise money for a study to develop a fairer system.

The last system we will consider is the Residential Equivalent Factor or REF system. This model estimates the runoff for a single-family residential property and takes the ratio of runoff from nonresidential properties per acre to runoff from single family residential properties per acre. The fee multiplies this ratio times the size of the parcel to get the fee. This sounds almost ideal. Though there is a strong correlation between impervious area and stormwater runoff produced, the correlation is not perfect. So it would seem that a REF system would be ideal. However, there are many ways to tweak runoff to favor or disfavor any property class. Some basic hydrology is needed to clarify this statement.

The Natural Resources Conservation Service (NRCS), formerly the Soil Conservation Service (SCS) divides soils into four hydrologic soil groups, A, B, C, and D. Type A soils are primarily sand and gravel which allows rainfall to soak quickly into the ground. Type D soils are silts and clays that absorb rainfall much less readily. Types B and C are intermediate to the two ends of the spectrum. Surface runoff occurs much more readily in a type D soil than in a type A soil.

The next important concept introduced by the NRCS is the runoff curve number or CN. It is a number that falls between zero and 100 which is based on land use and hydrologic soil group. For our example we will use types A, B, C, and D soils for residential 1/3 acre lots and commercial lots. Table 1 gives these values.

Table 1. Runoff curve numbers.

Land Use	Hydrologic Soil Group			
	A	B	C	D
Residential 1/3 acre	57	72	81	86
Commercial	89	92	94	95

When rainfall begins initially there is no runoff because water is held on vegetation and bound by surface tension to surfaces or is stored in depressions. The amount of rainfall that must occur before runoff begins is called the initial abstraction I_a . Once runoff begins there is a maximum amount of rainfall that can be held on plants, soak into the ground, or held in surface depressions. This is called the potential maximum retention S . Surface runoff is modeled by the NRCS in terms of these 3 quantities as shown in the 3 equations below.

$$S = \frac{1000}{CN} - 10 \quad (6)$$

$$I_a = 0.2S \quad (7)$$

$$Q = \frac{(P - I_a)^2}{P + 0.8S} \quad (8)$$

In these equations P is the rainfall in inches, and Q is the surface runoff in inches. With this background we can now address the REF fee system. To get the runoff from a typical single family residential lot the hydrologic soil group, the typical single family residential parcel type, and the standard storm must be chosen. Herein lies the problem. Presumably, a predominant soil type can be chosen for residential properties though B and C soil types are the most common. Which do you choose? You could average single family residential parcel square footage to determine if 1/3 acre, smaller, or larger is appropriate. The rub comes in choosing the standard storm. If you choose something like the rainfall with a 1-year return period, then commercial properties will be penalized. If you choose the 100-yr storm then residential property owners will be penalized. Different standard storms are used in different communities. We believe that choosing a standard storm is not likely to capture fairly the relative stormwater runoff production of residential versus commercial properties. A fairer way to do this is to take several years of rainfall data and use Equations 6 to 8 determine the total runoff and then take the ratio of different land uses to that for the typical single family residential land use. Though this is the fairest way to do this, to our knowledge no one does it.

To see the differences the choice of soil type and the ratios of runoff for commercial to residential properties we collected several years of rainfall data for Bowling Green, Kentucky and Las Vegas, Nevada. We calculated daily runoff over these years for each soil type and plotted the ratio of commercial runoff to residential runoff as a function of days of runoff. These plots are provided in Figures 8 and 9. We chose two very different climate types. Bowling Green gets about 50 inches of

rainfall in an average year and Las Vegas is one of the driest cities in the country. In Bowling Green if we chose the very uncommon type A soil the ratio of commercial to residential runoff is approximately 12 meaning that a commercial property would be paying 12 times as much per acre as a residential property. If we chose a type B soil the ratio would be about 4 and for type C about 3. The choice of soil type is very important.

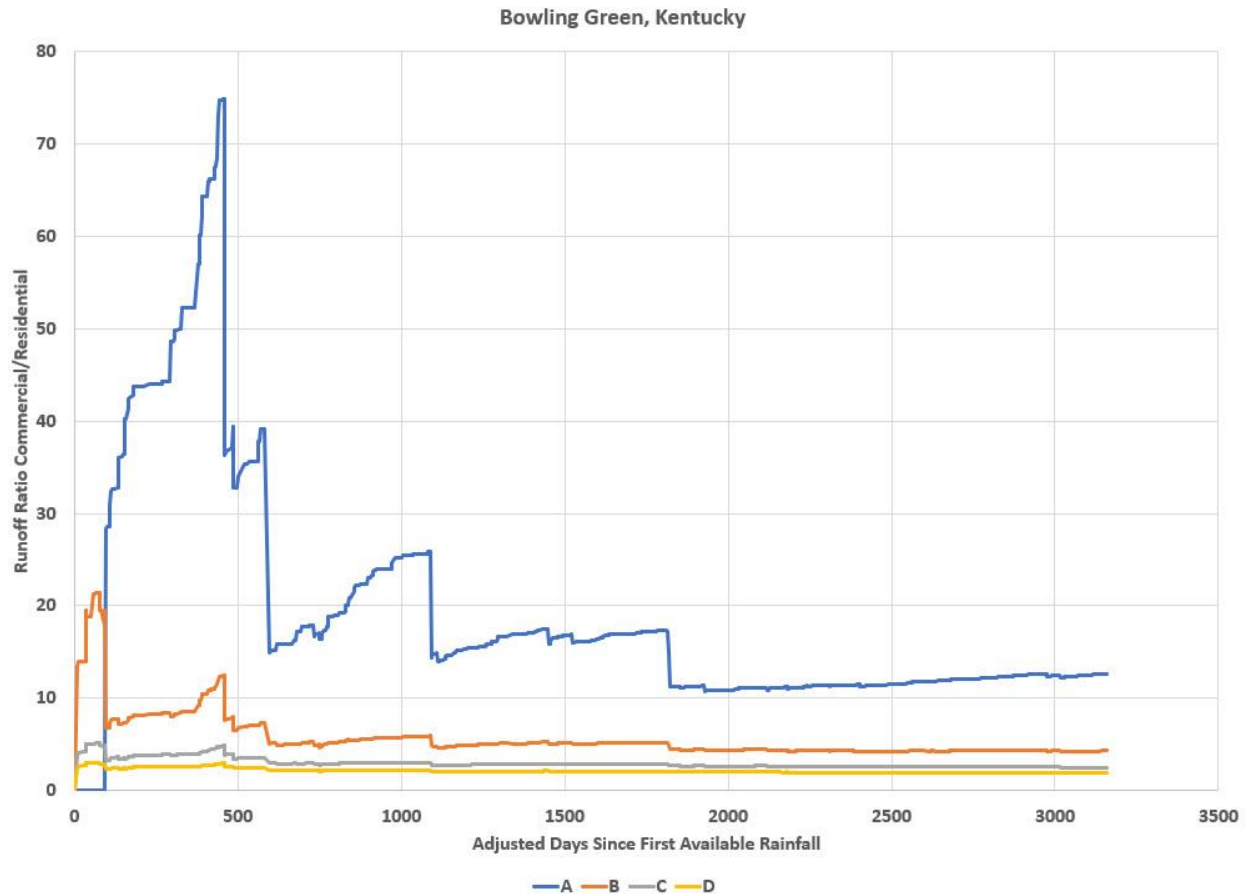

Figure 8. Runoff ratios for Bowling Green, Kentucky for all soil types.

To overcome the difficulty of achieving equilibrium in Las Vegas for type A soils, the empirical rainfall probability distribution was used for Monte Carlo simulation of daily rainfall amounts. More than 3000 days of measurable and measured rainfall were available from NOAA. These were used to develop a cumulative probability distribution of daily rainfall. Using this empirical probability distribution, 10,000 days of rainfall were simulated. When this was repeated even then the above curve did not reach equilibrium for type A soils. The reason for this is that only on about 0.17 percent of days was there enough rain to exceed the initial abstraction for type A soils. This means that on average only 17 days resulted in runoff in 10,000 days of rainfall. The 10,000 rain day simulation was repeated 100 times so that in all one million days of rainfall were simulated. The 100 ratios for each soil were averaged and standard deviations obtained. The ratios for the different soil types are provided in Table 2 along with uncertainties to within \pm one standard deviation. The values and the standard deviations of the estimates are given in the table. Note that the standard deviations given are the standard deviations of the ratios for the 100 simulations of 10,000 rainfall days each. These standard deviations should be

divided by a factor of $10 = \sqrt{100}$ because we have a sample of 100 simulations. The worst uncertainty is for the type A soils which is approximately 169 ± 14 . Similarly the ratio for type B soils is about 24 ± 0.4 . For type C soils the ratio is 7.9 ± 0.0488 , and for type D soils 4.37 ± 0.015 . These values are much higher than for Bowling Green. This result is expected since Bowling Green gets much heavier rainfall.

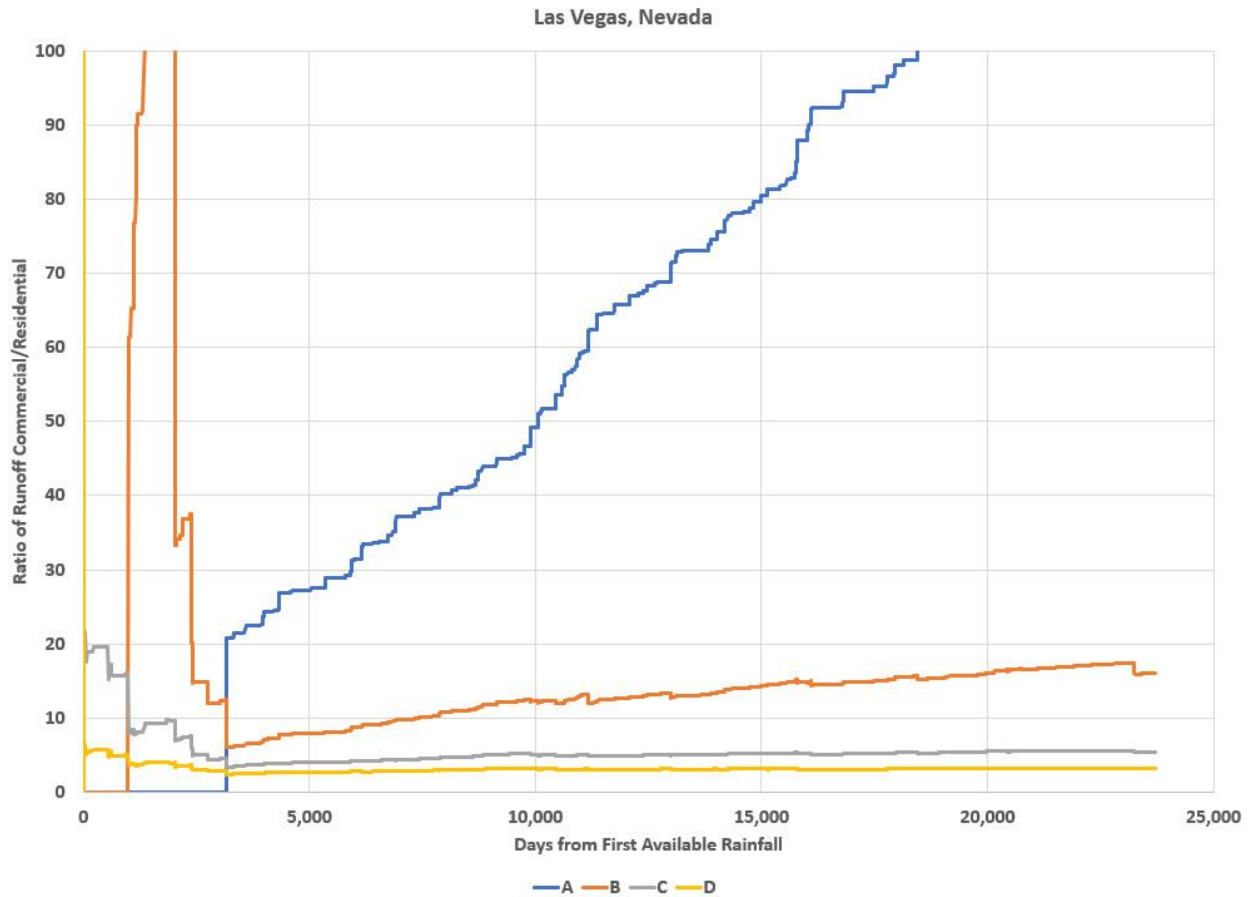

Figure 9. Runoff ratios for Las Vegas, Nevada for all soil types.

Table 2. Final runoff ratios of commercial to residential parcels for Las Vegas

Mean	168.6999	23.91961	7.900946	4.369585
Std Dev	139.7419	3.936748	0.482178	0.148264

Summary

Pennsylvania continues to lead the nation in formation of new stormwater utilities. We have identified 59 of them. All but one of these formed within the past decade. They continue to form in Canada as well.

However, the U.S. and Canada are not the only countries with stormwater fees. They have formed in Australia, Brazil, Ecuador, France, Germany, Poland, and South Africa as well (Tasca, et al., 2017).

Stormwater utilities can be made fair so that large producers of stormwater pay the most. However, they can be unfair as well. Flat fee and dual fee systems are not fair. They are simple and easy to administer. However, in a flat fee system a Walmart with 750,000 square feet of impervious area pays the same as a 500 square foot bungalow. ERU, tier, and REF systems were examined to show how they can be made fair or unfair. The fairness of stormwater fees for most stormwater utilities can be improved by the methods described here. Doing this should also reduce legal exposure of the utilities.

To make an ERU fee system fair, use an accurate ERU. To make a tier system fair, use the method described in equations 3 through 5 to construct the impervious area tiers and choose the tier fees. For a REF system, compare runoff for several years of rainfall data for the different land uses. Use flat fee and dual fee systems only to raise money to support the preparation of fairer fee systems.

Appendix A. Raw Data Tables

The following data tables provide the information collected on 2057 U.S. stormwater utilities and 62 Canadian ones. Note that ERUs in the Canadian SWUs are in square meters impervious. The key for the fee types is given below.

Code	Meaning
IA	Impervious Area
E	ERU
F	Fixed Rate
T	Tier System
R	Residential Equivalence Factor (or similar)
D	Two Level System (Residential/Commercial)
X	No information
S	Fee per Parcel Square Footage
A	Fee per Parcel Acre
-	Repealed
M	Water Meter
W	By Water Usage
AV	Ad valorem fee
LU	Land use based fee
ID	Intensity of development
Z	Zoning
PT	Parking spaces in tiers

Table A-1. U.S. Stormwater Utility Database

No.	Community	State	Fee Type	ERU (ft2)	Monthly Fee	Year Created	Population
1	Anniston	AL	IA		\$0.83	2014	22,112
